(57) This method and apparatus simulates a pattern of wave energy radiated to an observation point in space by a scanning phased array antenna. A beam steering unit provides phase angle data at set time intervals to phase shifters associated with elements of the antenna. Simulation involves storing initial phase angle data in discrete memory areas associated with individual phase shifters. This data is repeatedly updated in accordance with phase angle data from the beam steering unit. Observation angle data is generated which is functionally related to wavelength; distance between antenna elements; and a selected angle at which the pattern of wave energy radiated to an observation point in space is to be simulated. Observation angle data is combined with the updated phase angle data and used to produce functionally related composite angle data. From this is subtracted the composite angle data from the previous time interval, and to which is added initial composite angle data to provide accumulated composite angle data. A function of the latter determines the relative amplitude of wave energy which is radiated to an observation point in space at the selected angle.

COMPLETE SPECIFICATION

BEAM STEERING UNIT REAL TIME ANGULAR MONITOR

We, HAZELTINE CORPORATION, a corporation organized and existing under the laws of the State of Delaware, United States of America of <sup>Greenlawn</sup> 500 ~~Cornack~~ Road, Cornack, New York 11725, United States of America, do hereby declare the invention, for which we pray that a Patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:-

- 1 - (followed by 1A)

BACKGROUND OF THE INVENTIONField of the Invention

The present invention relates to a method of and a system for monitoring the operation of a beam steering unit for a phased array antenna, during a scanning operation of the beam steering unit. In particular, according to the invention, the pattern of wave energy which would be radiated from the antenna to an observation point in space during the scanning operation is simulated by processing phase angle data provided by the beam steering unit and combining it with observation angle data corresponding to the observation point.

Description of the Known Art

In order to verify proper operation of a beam steering unit associated with a scanning phased array antenna, it has ordinarily been required to monitor the wave energy actually radiated by the antenna to near and/or far observation point, and then compare the monitored energy levels with a reference standard. For example, in United States patent 4,520,361 issued May 28, 1985, to R.F. Frazita and assigned to the assignee of the present invention, phase angle data provided from a beam steering unit to each of a number of radiating elements of a phased array antenna, is verified separately for each of the elements by coupling some of the element radiation to a manifold at the antenna, mixing the manifold output with a sample of the RF power source to obtain a beat frequency signal, and measuring the phase shift between the beat frequency signal and a reference pattern signal.

1        United States patent 4,536,766 issued August 20,  
2        1985, to R.F. Frazita and assigned to the assignee of  
3        the present invention, discloses a beam pointing  
4        correction arrangement which also entails the use of a  
5        manifold proximate the radiating elements of a scanning  
6        phased array antenna, wherein the manifold output is  
7        detected and decoded to provide an indication of the  
8        actual beam pointing angle. The start and stop time of  
9        the beam steering unit scanning operation is then  
10       adjusted to eliminate or minimize any detected beam  
11       pointing error. A system is also known from United  
12       States patent 4,532,517 issued July 30, 1985, in which  
13       output data from a beam steering unit is subjected to a  
14       cyclic redundancy check employing algebraic methods  
15       commonly used to verify accuracy of information  
16       transmitted in digital form.

17       . As far as is known, no method or system has been  
18       disclosed by which the pattern of wave energy radiated  
19       from a phased array antenna to an observation point  
20       during operation of an associated beam steering unit,  
21       can be simulated to allow for a comparison with a  
22       standard reference pattern. The desirability for such a  
23       method or system is especially great in microwave  
24       landing systems (MLS) in which precise timing of the  
25       beam steering operation must be maintained continuously  
26       to assure that an aircraft at a certain point in space  
27       relative to the system antennas will receive the antenna

1 beams at the proper timings as the antenna beams are  
2 scanned "to and fro" and "up and down".

3 Basically, a MLS employs at least two phased  
4 array antennas each having a number of equally spaced  
5 radiating elements which are excited with microwave  
6 energy at a generally uniform amplitude but at a phase  
7 determined by the setting of individual phase shifters  
8 associated with the elements. The function of setting  
9 the phase shifts for the individual phase shifters is  
10 accomplished by the beam steering unit (BSU). As is  
11 well-understood by those skilled in the art, a main  
12 energy beam which is radiated from the excited antenna  
13 elements can be steered or scanned in a direction  
14 relative to the antenna, in accordance with  
15 predetermined incremental changes of the phase shifters  
16 by the BSU over successive time intervals.

17 In MLS applications, an azimuth (AZ) phased array  
18 antenna scans its radiated beam to and fro periodically  
19 in the horizontal direction, the beam-width being  
20 relatively broad in the vertical direction but narrow in  
21 the horizontal direction, so that an aircraft within the  
22 scanning field of the AZ antenna will be able to detect  
23 a passage of the scanning beam from the AZ antenna from  
24 ground level to a relatively high altitude. An  
25 elevation (EL) phased array antenna scans its beam up  
26 and down periodically in the vertical direction, the  
27 beam width being relatively broad in the horizontal

1 direction but narrow in the vertical direction, so that  
2 an aircraft within the scanning field of the EL antenna  
3 will be able to detect the passage of the scanning beam  
4 from the EL antenna from an approach which is head-on to  
5 the antenna to one which is about  $\pm 40^\circ$  relative to the  
6 antenna axis.

7 Prior to a scanning operation of the AZ antenna,  
8 a "preamble" signal is radiated broadly from a third  
9 antenna for reception by an aircraft within the  
10 operating range of the MLS. The preamble signifies,  
11 inter alia, that a horizontal scan of the beam from the  
12 AZ antenna is to begin at a certain time from one side  
13 (e.g.,  $-40^\circ$ ) of the AZ antenna, to the opposite side  
14 ( $+40^\circ$ ), and back again to the starting side ( $-40^\circ$ ).  
15 Equipment on board the aircraft detects and decodes the  
16 preamble, and counts the time period between reception  
17 of the beam from the AZ antenna on its "to" scan and  
18 reception of the beam on the "fro" scan. The counted  
19 time difference corresponds to a unique azimuth heading  
20 of the aircraft relative to the AZ antenna. The MLS  
21 then broadly radiates a preamble signifying that a  
22 scanning operation of the EL antenna is about to begin  
23 and, by a corresponding time difference counting  
24 operation, the equipment on board the aircraft  
25 determines a unique elevation angle for the craft  
26 relative to the EL antenna. Since both the AZ and EL  
27 antennas are located in the vicinity of a runway

1 employing the MLS, the aircraft pilot thus receives  
2 information which is critical to assure a proper glide  
3 path for a safe landing on the runway.

4 From the foregoing, it will be appreciated that  
5 precise timing of the scanning operations of both the AZ  
6 and EL antennas is essential to ensure accurate glide  
7 path information will be provided to the aircraft  
8 pilot. Any malfunction which results in a deviation of  
9 the time difference between to and fro or up and down  
10 scanning beams at a given point in space, from a  
11 predetermined difference which defines the location of  
12 the point in space when the MLS is functioning properly,  
13 will cause the on-board equipment to produce erroneous  
14 heading information.

15 A major source of such potential system  
16 malfunction is the BSU which controls the direction and  
17 rate of scan of the beams from the AZ and EL antennas in  
18 the MLS. Thus, it is imperative that the BSU be  
19 monitored continuously with respect to the phase angle  
20 data which it provides to the phase shifters associated  
21 with the antenna elements, causing the beams to be swept  
22 at the desired predetermined rates.

### 23 SUMMARY OF THE INVENTION

24 An object of the present invention is to overcome  
25 the above and other shortcomings in the known techniques  
26 by which operation of a BSU can be monitored in real

1 time.

2 Another object of the invention is to provide a  
3 technique by which the accuracy of the BSU can be  
4 ascertained without providing field monitors in the  
5 vicinity of or at points located remote from the antenna  
6 with which the BSU is associated.

7 A further object of the invention is to simulate,  
8 in real time, the pattern of wave energy which would be  
9 radiated to an aircraft from a MLS antenna during  
10 operation of the associated BSU.

11 A further object of the invention is to simulate,  
12 in real time, the scanning of a beam of a MLS antenna as  
13 received by an aircraft at a certain point in space  
14 during a scanning operation of the BSU, and to compare  
15 the time difference between successive beams with a  
16 preset time difference to confirm proper operation of  
17 the BSU.

18 According to one aspect of the present invention,  
19 a method of simulating the pattern of wave energy which  
20 would be radiated to an observation point in space from  
21 a scanning phased array antenna during operation of the  
22 BSU, includes storing initial phase angle data in memory  
23 areas each of which corresponds to a phase shifter to be  
24 driven by the BSU, sequentially reading out phase angle  
25 data from the memory areas and updating the phase angle  
26 data from each area according to the phase angle data  
27 from the BSU and storing the updated phase angle data in

1 the corresponding memory areas, selecting a desired  
2 observation angle relative to the antenna whereat the  
3 wave energy pattern radiated from the antenna to a point  
4 at the observation angle is to be simulated and  
5 generating observation angle data which is related to  
6 (a) the desired observation angle, (b) the distance  
7 between adjacent antenna elements and (c) the wavelength  
8 of the wave energy, combining the updated phase angle  
9 data with the observation angle data and producing  
10 composite angle data functionally related to the  
11 combined data, subtracting from the composite angle data  
12 for a time interval of the BSU operation, the composite  
13 angle data for the immediately preceding time interval  
14 and accumulating resulting differences with initial  
15 value composite angle data to provide accumulated  
16 composite angle data, and determining the relative  
17 amplitude of wave energy which would be radiated to the  
18 point at the desired observation angle during BSU  
19 operation as a function of the accumulated composite  
20 angle data.

21 According to another aspect of the invention, a  
22 system for testing the operation of a BSU by simulating  
23 the wave energy pattern which would be radiated to an  
24 observation point from a scanning phased array antenna  
25 having phase shifters associated with equally spaced  
26 elements of the antenna, includes memory means for  
27 storing phase angle data provided by the BSU at certain

1 time intervals in memory areas each corresponding to a  
2 phase shifter to be driven by the BSU, logic means  
3 coupled to the memory means and adapted to be responsive  
4 to the phase angle data from the BSU for addressing and  
5 controlling data flow in and out of the memory areas,  
6 the logic means including means to set initial phase  
7 angle data in the areas of the memory means to  
8 correspond with initial phase settings for the phase  
9 shifters, data increment means coupled to the memory  
10 means for updating the value of phase angle data when  
11 read out of each of the memory areas according to the  
12 phase angle data from the BSU, wherein the updated phase  
13 angle data is stored in corresponding memory areas for  
14 each time interval, means for generating observation  
15 angle data according to a selected angle at which the  
16 observation point is located relative to the antenna,  
17 the observation angle data being functionally related to  
18 the selected observation angle, the spacing between  
19 adjacent antenna elements and the wavelength of the wave  
20 energy, means coupled to the data increment means and  
21 the observation angle data generating means for  
22 combining the updated phase angle data with the  
23 observation angle data, and producing composite angle  
24 data as a function of the combined data, means for  
25 subtracting from the composite angle data for each time  
26 interval the composite angle data for the immediately  
27 preceding time interval, means coupled to the

1 subtracting means for accumulating resulting differences  
2 with initial value composite angle data to produce  
3 accumulated composite angle data, and means for  
4 determining the relative amplitude of wave energy which  
5 would be radiated to the observation point during  
6 scanning of the BSU according to the accumulated  
7 composite angle data, and for producing a corresponding  
8 output.

9 For a better understanding of the present  
10 invention, together with other and further objects,  
11 reference is made to the following description taken in  
12 conjunction with the accompanying drawing, and the scope  
13 of the present invention will be pointed out in the  
14 appended claims.

15 BRIEF DESCRIPTION OF THE DRAWING

16 In the drawing:

17 Figure 1 is a conceptual block diagram of a  
18 system for testing operation of a BSU<sup>10</sup> according to  
19 the invention;

20 Figure 2A is a block diagram of a BSU interface  
21 portion 12a of an antenna pattern simulator 12 according  
22 to the invention; and

23 Figure 2B is a block diagram of a phase angle and  
24 observation angle processing portion 12b of the present  
25 antenna pattern simulator 12.

BEAM STEERING UNIT REAL TIME ANGULAR MONITOR

DETAILED DESCRIPTION OF THE INVENTION

Figure 1 represents a technique for monitoring in real time a pattern of wave energy which would be radiated to a given point in space by a phased array antenna which is scanned by a given beam steering unit (BSU) 10. The beam steering unit may be, for example, one which is intended for MLS applications such as, e.g., the type MLS 2600 manufactured by Hazeltine Corporation of Commack, New York. The BSU may have separate phase angle data outputs  $\phi A$  and  $\phi B$  corresponding to differential phase angle information to be conveyed to phase shifters associated with an "A" (azimuth) and (elevation) a "B" side of a MLS phased array antenna. The differential phase data supplied by the BSU 10 during a scanning operation is coupled to an array antenna pattern simulator 12, rather than or in addition to the phase shifters of the MLS antenna. As explained below in regard to Figures 2A and 2B, the simulator 12 will appear to the BSU 10 as the phase shifters themselves insofar as the addressing and phase angle data outputting functions of the BSU are concerned.

By processing the phase angle data provided by BSU 10 and observation angle data generated upon setting of an observation angle select switch 14, the simulator 12 provides a digital-to-analog converted output signal

1 which, if connected to the V input of an oscilloscope  
 2 16, causes a real time display of a MLS antenna beam  
 3 were the antenna to be steered by the BSU. A "start  
 4 scan" signal provided from the BSU 10 to the trigger (T)  
 5 terminal of the scope 16 thus would cause the display to  
 6 represent the time at which the main scanning beam of  
 7 the antenna would be received at an observation point at  
 8 the selected angle, after the start of a single scan.

9 Assuming that the phased array antenna to be  
 10 associated with the BSU 10 comprises a number (e.g.,  
 11 112) of equally spaced, uniformly illuminated radiating  
 12 elements, the far-field pattern of the antenna at a  
 13 point in space at an angle  $\theta$  relative to the antenna  
 14 axis can be represented by

$$15 \quad \Sigma \exp j \left( \frac{2\pi}{\lambda} nd \sin \theta + \phi_n \right)$$

16 wherein:  $n$  is the element number  
 17  $d$  is the spacing between elements  
 18  $\phi_n$  is the relative phase shift  
 19 introduced to the  $n$ th  
 20 element by its associated  
 21 phase shifter, and  
 22  $\lambda$  is the wavelength of energy to  
 23 be radiated by the antenna.

24 Expansion of the foregoing yields:

$$25 \quad \Sigma (\cos x_n + j \sin x_n),$$

26 where:  $x_n = 2 \frac{\pi}{\lambda} nd \sin \theta + \phi_n$ .

1 The relative power at the observation point  
2  $\theta$  thus may be expressed as:

3 
$$|\sum \cos x_n|^2 + |\sum \sin x_n|^2.$$

4 By obtaining a continuous real time summation of  
5 the values for the  $\cos(x_n)$  and the  $\sin(x_n)$  for all the  
6 antenna elements or phase shifters  $n$ , squaring the sums  
7 and then summing the squares, the relative power  
8 radiated by the antenna to the far-field observation  
9 point at the set angle  $\theta$  is obtained.

10 Each of the  $\phi_n$  may be changed or updated at a  
11 rate of, e.g., 5 MHz or every 200 nanoseconds as in the  
12 MLS 2600 BSU. The summations must therefore be  
13 performed, then squared and added to one another as the  
14 values are updated to enable a faithful reproduction of  
15 the scanning pattern which would be obtained at the  
16 observation point.

17 The antenna pattern simulator 12 of Figures 2A  
18 and 2B performs the necessary operations on the phase  
19 angle data from the BSU 10 as updated, without the  
20 requirement for a large summing network having inputs  
21 (e.g., 112) corresponding to the settings of phase  
22 shifters coupled to the BSU output.

23 The BSU interface portion 12a of Figure 2A  
24 includes control logic 20 for buffering the output from  
25 the BSU 10 and supplying it to a random access memory 22  
26 having memory areas the addresses of which correspond to

1 phase shifters which would be driven by the BSU 10 when  
2 operating with a phased array antenna. As mentioned,  
3 the BSU 10 provides only differential phase angle data,  
4 i.e., data indicative of the change, if any, to be made  
5 to a particular phase shifter setting from the setting  
6 of the immediately preceding update interval. In actual  
7 practice, the BSU 10 provides initial absolute value  
8 phase shift settings for each of the n phase shifters,  
9 followed by differential data in, e.g.,  $22 \frac{1}{2}^\circ$   
10 increments to alter the phase shifter settings up or  
11 down in certain time intervals. In Figure 2A, the  
12 initial setting phase angle data is transferred through  
13 control logic 20 directly to the memory areas of RAM 22  
14 corresponding to the phase shifters to be set. The  
15 contents of the memory areas are then successively added  
16 in adder 24 to any differential phase angle data  
17 produced by BSU 10 as passed by control logic 20 to a  
18 second input of adder 24. Since no differential data is  
19 provided at the start of a scan, the initial phase  
20 shifter setting data is unaffected and passed to an  
21 input of a second adder 26. The remaining input of  
22 adder 26 is coupled to a universal preset/count circuit  
23 28 which provides a function corresponding to one which  
24 is available on MLS antennas and well-known in the  
25 art. The adder 26 and circuit 28 may, however, be  
26 eliminated in some cases.

1           When the first differential data for a phase  
2 shifter n is provided from BSU 10, it is routed to adder  
3 24 wherein the previous (or initial) phase angle data  
4 for the phase shifter n is incremented according to the  
5 differential data. The result is stored at the memory  
6 area corresponding to the phase shifter n in the RAM 22,  
7 and provided to the second adder 26 or directly as out-  
8 put data corresponding to the absolute phase shift value  
9 set in each phase shifter n during a time interval t.

10           Each time new differential data for a phase  
11 shifter n is produced by the BSU 10, it is combined in  
12 the adder 24 with the immediately previous absolute  
13 phase shift value as stored in the corresponding memory  
14 area in RAM 22, and the thus incremented (or  
15 decremented) absolute value data is rewritten in the  
16 same memory area while being provided as output data  
17 from the interface portion of Figure 2.

18           Figure 2B is a phase shifter angle and  
19 observation angle processing portion 12b of an antenna  
20 pattern simulator 12 according to the invention.

21           An observation angle select circuit 30 which may  
22 be in the form of DIP switches is connected to a  
23 programmable observation angle memory (PROM) 32. PROM  
24 32 provides an output corresponding to the sine of the  
25 selected observation angle  $\theta$  multiplied by the antenna  
26 element spacing d, the factor  $\frac{2\pi}{\lambda}$ , and the phase shifter  
27 number n. The result is combined in adder 34 with the

1 absolute phase setting for each phase shifter  $n$  to  
2 produce composite phase angle data for the phase shifter.  
3  $n$  at a given update interval  $t$ . In order to carry out  
4 the required summations of the cosine and the sine of  
5 the composite angle data, differences between the cosine  
6 of said data for a phase shifter  $n$  at a time interval  $t$   
7 and the data for the same phase shifter  $n$  at the  
8 immediately preceding time interval  $(t-1)$  are determined  
9 by cosine circuit 36 and supplied for each of the phase  
10 shifters to a cosine accumulator circuit 38. A sine  
11 subtraction circuit 40 and sine accumulator circuit 42  
12 carry out similar operations for the required sine  
13 summation. An output  $I$  of cosine accumulator 38  
14 corresponds to the sum of the in-phase field  
15 contributions of each phase shifter (antenna element)  $n$   
16 at a far-field point at the selected observation  
17 angle. An output  $Q$  of the sine accumulator 42  
18 corresponds to the quadrature far field effects of the  
19 antenna elements as combined. By squaring each of the  $I$   
20 and  $Q$  outputs, summing the squares and taking the Log of  
21 the result, a signal  $P$  corresponding to the relative  
22 power at the observation point during a scanning  
23 operation of the BSU 10 is produced. Since the signal  $P$   
24 is in digital form, it may be necessary to provide a D/A  
25 converter 46 to provide a corresponding analog signal  
26 for observation and/or further processing.

1           It will be appreciated that in accordance with  
2     the invention, the absolute phase angle settings for  
3     each of a great number of phase shifters is stored in  
4     corresponding memory areas of the RAM 22. The in-phase  
5     and quadrature far field effect of each phase shifter at  
6     a certain observation angle is determined and  
7     accumulated in the accumulators 38, 42 at the start of a  
8     scanning operation of the BSU 10. As differential phase  
9     angle data is produced by the BSU 10, the previous field  
10    contribution of each phase shifter is subtracted by the  
11    circuits 36, 40 from the new contribution and the result  
12    accumulated.

13           A highly desirable instrument for monitoring the  
14    operation of phased array antennas with a particular  
15    beam steering unit is disclosed herein, with a  
16    relatively small amount of circuit devices required for  
17    its implementation.

18           While the foregoing description represents a  
19    preferred embodiment of the invention, it will be  
20    obvious to those skilled in the art that various changes  
21    and modifications may be made, without departing from  
22    the true scope and spirit of the invention.

## WHAT WE CLAIM IS:

1           Claim 1. A method of simulating the pattern of  
2 wave energy which would be radiated to an observation  
3 point in space from a scanning phased array antenna  
4 during operation of an associated beam steering unit,  
5 the beam steering unit providing phase angle data at  
6 certain time intervals to set a number of phase shifters  
7 associated with elements of the phased array antenna,  
8 comprising the steps of:  
9           storing initial phase angle data in memory  
10 areas each of which corresponds to a phase shifter to be  
11 driven by the beam steering unit;  
12           sequentially reading out phase angle data  
13 from said memory areas and updating the phase angle data  
14 from each memory area in accordance with the phase angle  
15 data from the beam steering unit, and storing the  
16 updated phase angle data in the corresponding memory  
17 areas over each successive time interval;  
18           selecting a <sup>desired</sup> observation angle relative to  
19 the antenna at which the pattern of wave energy radiated  
20 from the antenna to a point in space at said selected  
21 observation angle is to be simulated during a scanning  
22 operation of the beam steering unit;  
23           generating observation angle data which is  
24 functionally related to the selected observation angle,  
25 the distance between adjacent antenna elements and the  
26 wavelength of the wave energy;

27 combining the updated phase angle data for  
28 each time interval with the observation angle data and  
29 producing composite angle data which is a function of  
30 the combined data;

31 subtracting from the composite angle data  
32 for each time interval the composite angle data for the  
33 immediately preceding time interval and accumulating  
34 resulting differences with initial value composite angle  
35 data to provide accumulated composite angle data; and

36 determining the relative amplitude of wave  
37 energy which would be radiated to the point in space at  
38 the selected observation angle during operation of the  
39 beam steering unit as a function of the accumulated  
40 composite angle data.

1 Claim 2. The method of claim 1, wherein the step  
2 of producing the composite angle data includes  
3 generating separate data corresponding to the cosine and  
4 the sine of the combined updated phase angle data and  
5 observation angle data, thereby generating composite  
6 cosine data and composite sine data.

1 Claim 3. The method of claim 2, wherein said  
2 subtracting and accumulating step includes:  
3 subtracting from the composite cosine data  
4 for each time interval the composite cosine data for the  
5 immediately preceding time interval and accumulating

6 resulting differences with initial value composite  
7 cosine data to provide accumulated composite cosine  
8 data, and  
9 subtracting from the composite sine data for  
10 each time interval the composite sine data for the  
11 immediately preceding time interval and accumulating  
12 resulting differences with initial value composite sine  
13 data to provide accumulated composite sine data.

1 Claim 4. The method of claim 3, wherein said  
2 relative amplitude determining step includes:  
3 squaring the accumulated composite cosine  
4 data,  
5 squaring the accumulated composite sine  
6 data, and  
7 adding the squared accumulated composite  
8 cosine data to the squared accumulated composite sine  
9 data.

1 Claim 5. The method of claim 1, including  
2 comparing the determined relative amplitude of wave  
3 energy with a preset pattern during a scanning operation  
4 of the beam steering unit, and providing an indication  
5 when a certain difference between the determined  
6 amplitude and the preset pattern is exceeded.

1           Claim 6. The method of claim 5, including  
2     selecting a number of different observation angles and  
3     performing said comparing step for each of the selected  
4     observation angles.

1           Claim 7. A system for testing the operation of a  
2     beam steering unit by simulating the pattern of wave  
3     energy which would be radiated to an observation point  
4     in space from a scanning phased array antenna including  
5     phase shifters associated with substantially equally  
6     spaced elements of the antenna, the beam steering unit  
7     providing phase angle data at certain time intervals to  
8     set the phase shifters over a scanning operation,  
9     comprising:

10                 memory means for storing phase angle data in  
11     memory areas each corresponding to a phase shifter to be  
12     driven by the beam steering unit;

13                 logic means coupled to said memory means and  
14     adapted to be responsive to the phase angle data  
15     provided by said beam steering unit, for addressing and  
16     controlling data flow into and out of said memory areas,  
17     said logic means including means for setting initial  
18     phase angle data in the areas of said memory means to  
19     correspond with initial phase settings for the phase  
20     shifters prior to a scanning operation of the beam  
21     steering unit;

22 data increment means coupled to said memory  
23 means for updating the value of phase angle data when  
24 read out of each of said memory areas in accordance with  
25 the phase angle data from the beam steering unit, the  
26 updated phase angle data being stored in the  
27 corresponding memory area by said logic means for each  
28 successive time interval;

29 means for generating observation angle data  
30 in accordance with a selected observation angle at which  
31 said observation point is located relative to the  
32 antenna, said observation angle data being functionally  
33 related to the selected observation angle, the spacing  
34 between adjacent antenna elements and the wavelength of  
35 the wave energy;

36 means coupled to said data increment means  
37 and said observation angle data generating means for  
38 combining the updated phase angle data for each time  
39 interval with the observation angle data, and for  
40 producing composite angle data which is a function of  
41 the combined data;

means coupled to said means for combining the  
updated phase angle data, for subtracting from the composite  
angle data for each time interval the composite angle  
data for the immediately preceding time interval;

means coupled to said subtracting means for  
accumulating resulting differences with initial value  
composite angle data to produce accumulated composite angle  
data; and

49 means coupled to said accumulating means for  
50 determining the relative amplitude of wave energy which  
51 would be radiated to said observation point during a  
52 scanning operation of the beam steering unit in  
53 accordance with said accumulated composite angle data,  
54 and for producing a corresponding output.

1 Claim 8. A system according to claim 7, wherein  
2 said combining and producing means includes means for  
3 producing separate data corresponding to the cosine and  
4 the sine of the combined updated phase angle data and  
5 observation angle data, to define composite cosine data  
6 and composite sine data.

1 Claim 9. A system according to claim 8, wherein  
2 said subtracting means includes:  
3 first means for subtracting from the  
4 composite cosine data for each time interval the  
5 composite cosine data for the immediately preceding time  
6 interval, and

7 second means for subtracting from the  
8 composite sine data for each time interval the composite  
9 sine data for the immediately preceding time interval,  
10 and

11 said accumulating means includes:

12 cosine accumulator means coupled to said  
13 first means for accumulating resulting differences with

22 0 2 7

14 initial value composite cosine data to produce  
15 accumulated composite cosine data, and  
16 sine accumulator means coupled to said  
17 second means for accumulating resulting differences with  
18 initial value composite sine data to produce accumulated  
19 composite sine data.

1 Claim 10. A system according to claim 9, wherein  
2 said relative amplitude determining means includes means  
3 for generating the square of said accumulated composite  
4 cosine data, means for generating the square of said  
5 accumulated composite sine data, and means for adding  
6 together the generated squares of said data.

1 Claim 11. A system according to claim 7,  
2 including means for storing a preset antenna pattern,  
3 means for comparing the output of said determining means  
4 with said preset antenna pattern during a scanning  
5 operation of the beam steering unit, and means for  
6 indicating when a certain difference between said output  
7 and said preset pattern is exceeded.

1 Claim 12. A Beam Steering Unit Real Time Angular  
2 Monitor of the type specified and substantially as  
3 illustrated in the accompanying drawings and described  
4 in the specification with reference thereto.
